

AI ASSISTED CODING

ASSIGNMENT-12.5

Name: Aravind Reddy

H.T.No:2303A51027

Task Description #1 (Sorting – Merge Sort Implementation) • Task: Use AI to generate a Python program that implements the Merge Sort algorithm. • Instructions: o Prompt AI to create a function `merge_sort(arr)` that sorts a list in ascending order. o Ask AI to include time complexity and space complexity in the function docstring. o Verify the generated code with test cases.

Expected Output:

o A functional Python script implementing Merge Sort with proper documentation.

```
#Generate a function merge_sort that takes a list as input and returns a sorted list
# using the merge sort algorithm also include time and space complexities in docstring and give 2 example testcases
def merge_sort(arr):
    """
    Sorts a list using the merge sort algorithm.

    Time Complexity:  $O(n \log n)$  - where  $n$  is the number of elements in the list.
    Space Complexity:  $O(n)$  - due to the temporary arrays used for merging.

    Parameters:
    arr (list): The list to be sorted.

    Returns:
    list: A sorted version of the input list.
    """
    if len(arr) <= 1:
        return arr

    mid = len(arr) // 2
    left_half = merge_sort(arr[:mid])
    right_half = merge_sort(arr[mid:])

    return merge(left_half, right_half)

def merge(left, right):
    """Merges two sorted lists into a single sorted list."""
    merged = []
    left_index = right_index = 0

    while left_index < len(left) and right_index < len(right):
        if left[left_index] < right[right_index]:
            merged.append(left[left_index])
            left_index += 1
        else:
            merged.append(right[right_index])
            right_index += 1
```

```

    # If there are remaining elements in left or right, add them to merged
    merged.extend(left[left_index:])
    merged.extend(right[right_index:])

    return merged
# Example test cases
if __name__ == "__main__":
    # Test case 1
    arr1 = [38, 27, 43, 3, 9, 82, 10]
    print("Original array:", arr1)

Task Description #2 (Searching – Binary Search with AI Optimization)

- Task: Use AI to create a binary search function that finds a target element in a sorted list.
- Instructions:
 - o Prompt AI to create a function `binary_search(arr, target)` returning the index of the target or -1 if not found.
 - o Include docstrings explaining best, average, and worst-case complexities.
 - o Test with various inputs.
- Expected Output:
 - o Python code implementing binary search with AI-generated comments and docstrings.

```

#Generate a function for binary search that searches for a target value in a sorted list and returns the index of the target value if found,
# otherwise returns -1.Include average,best and worst case time complexities in docstring and give 2 example testcases
def binary_search(arr, target):
    """
    searches for a target value in a sorted list using binary search algorithm.

    Time Complexity:
    - Average Case: O(log n) - where n is the number of elements in the list.
    - Best Case: O(1) - when the target value is at the middle of the list.
    - Worst Case: O(log n) - when the target value is not present in the list.

    Parameters:
    arr (list): A sorted list to search through.
    target: the value to search for.

    Returns:
    int: The index of the target value if found, otherwise -1.
    """
    left, right = 0, len(arr) - 1

    while left <= right:
        mid = left + (right - left) // 2

        # Check if the target is present at mid
        if arr[mid] == target:

Task Description #8: Airport Flight Management System An airport system stores flight information including flight ID, airline name, departure time, arrival time, and status.

The system must:

1. Search flight details using flight ID.
2. Sort flights based on departure time or arrival time.

Student Task

- Use AI to recommend algorithms.

- Justify the algorithm selection.
- Implement searching and sorting logic in Python.

```
